Cedar: scope and intake

Cedar is a fictional service for forest sensors. A Cedar request accepts at most 32 records. Input uses JSON Lines encoded as UTF-8. This is original synthetic test material, not the specification of a real product.

Cedar: execution

Cedar has a processing timeout of 9 seconds. Network failures are retried at most 4 times with exponential backoff. Invalid data is never retried.
Duplicate requests are rejected using request_id.

Cedar: storage

Cedar retains logs for 14 days. Guide A specifies a cache TTL of 60 seconds. The backup code is CEDAR-SAFE. Storage is in the local test region; no commercial geographic residency is promised.

Cedar: measurement table

Cedar test results:

Metric | Value

Accuracy | 94%

Latency p95 | 73 ms

Recovery time | 22 seconds

The test uses exactly 200 requests at concurrency 1. The author invented these values for document-reading tests. They are not Subject Knowledge Hub benchmark results.

Cedar: unresolved disagreement

Guide B for Cedar specifies a cache TTL of 75 seconds, unlike guide A. Neither guide has an effective date, so their precedence is unknown. Operators must verify the intended TTL. The document contains no rental price, support email address, or SLA.
